Asthma  
Inflammation  
NF-κB  
Toll-like receptors  
Oxidative stress  
Polyphenolic flavonoid compounds

Asthma is a complex inflammatory disease characterized by airway inflammation and hyperresponsiveness. The mechanisms associated with the development and progression of asthma have been widely studied in multiple populations and animal models, and these have revealed involvement of various cell types and activation of intracellular signaling pathways that result in activation of inflammatory genes. Significant contributions of Toll-like-receptors (TLRs) and transcription factors such as NF-κB, have been reported as major contributors to inflammatory pathways. These have also recently been associated with mechanisms of oxidative biology. This is of important clinical significance as the observed ineffectiveness of current available treatments for severe asthma is widely attributed to oxidative stress. Therefore, targeting oxidizing molecules in conjunction with inflammatory mediators and transcription factors may present a novel therapeutic strategy for asthma. In this review, we summarize TLRs and NF-κB pathways in the context of exacerbation of asthma pathogenesis and oxidative biology, and we discuss the potential use of polyphenolic flavonoid compounds, known to target these pathways and possess antioxidant activity, as potential therapeutic agents for asthma.

## 1. Introduction: immunology of allergic airway inflammation

The pulmonary system acts as the primary site of contact for pathogens and environmental pollutants. In its uncompromised state, this system exhibits a well-orchestrated interplay of components of both innate and adaptive immunity (Cruz & Koff, 2015; Martin & Frevert, 2005). The airways and alveolar epithelial cells are the first line of defense of the lung immune system, which not only presents the physical barrier against environmental insults, but also instructs the professional immune cells to protect from lung injury; whereas immune cells such as alveolar macrophages and neutrophils recognize and act to neutralize pathogens and foreign particles (Hoffmann et al., 2016).

Asthma is a complex inflammatory disease characterized by airway inflammation and remodeling, and airway hyperresponsiveness (AHR). The airways of asthmatic patients often present with infiltration of eosinophils, degranulated mast cells, and lymphocytes along with

hyperplasia of goblet cells and altered epithelial cell tight junctions (Curtis, 2005; Hoffmann et al., 2016). In this compromised state, the antigen presenting dendritic cells (DCs) recognize allergens and migrate to lymph nodes, where they present antigens to naïve CD4 T cells and induce their differentiation into various T helper (Th) cell types (e.g. Th1, Th2, Th17). In the case of allergic asthma, a predominance of Th2 cells is associated with the disease pathogenesis and progression (Chen & Kolls, 2013; Gaurav & Agrawal, 2013). A number of cytokines present in the environment influence the direction of T cell differentiation through interactions with receptors and activation of intracellular signaling cascades. Of these, toll-like receptors (TLRs), and transcription factors such as nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) play important roles in asthma pathogenesis, and in mechanisms leading to acute and chronic inflammation.

The TLR signaling pathways lead to the activation of transcription factors like NF-κB (through the IKKα/IKKβ), activator protein-1 (AP-1)

**Abbreviations:** COPD, chronic obstructive pulmonary disease; DAMPs, damage-associated molecular patterns; DC, dendritic cells; IFN, interferon; IKK (IKB), inhibitor kappa B kinase; IL, interleukins; MHC, major histocompatibility complex; MyD88, myeloid differentiation primary response protein MyD88; NADPH, nicotinamide adenine dinucleotide phosphate-oxidase; NEMO, NF-κB essential modifier; NF-κB, nuclear factor kappa-light-chain-enhancer of activated B cells; NIK, NF-κB-inducing kinase; O<sub>3</sub>, ozone; PAMPs, pathogen-associated molecular patterns; PRRs, pattern recognition receptors; RNS, reactive nitrogen species; ROS, reactive oxygen species; Th, T helper cell; TIR, Toll/IL-1R receptor domain; TIRAP, toll-interleukin 1 receptor (TIR) domain containing adaptor protein; TLR, Toll like receptors; TNF, tumor necrosis factor; TRIF, TIR-domain-containing adapter-inducing interferon-β; TSLP, Thymic stromal lymphoprotein

(through MAPKs) and Interferon Regulatory Factor (IRF)3 (through TBK1, IKK $\epsilon$  and IKK $\alpha$ ). Allergic asthma exhibits a crucial interplay of innate and adaptive immune functions, where NF- $\kappa$ B is considered as the master regulator of both innate and adaptive immune responses. Thus, the present review describes the role of TLRs and NF- $\kappa$ B in the context of asthma pathogenesis and oxidative biology as well as the use of polyphenolic flavonoid compounds targeting oxidants and signaling pathways as potential therapeutic agents for asthma.

## 2. Toll like receptors (TLRs)

The TLRs are a family of pattern recognition receptors (PRRs) known to possess key functions in innate immune responses (Aderem & Ulevitch, 2000; Akira, Takeda, & Kaisho, 2001). Toll-Like Receptors act by recognizing pathogen-associated molecular patterns (PAMPs) or damage-associated molecular patterns (DAMPs) by the distinct structural domains, and result in the activation of immune cells and pro-inflammatory cytokines. Long before the discovery of the TLRs, interleukin-1 (IL-1), a pleiotropic proinflammatory cytokine, was found to contribute to T cell activation and pyrogenicity (Dinarello, 1991). Although the IL-1 receptor (IL-1R) was already discovered, and the gene encoding the IL-1 receptor (IL-1R) was sequenced by the 1980s, the exact signaling mechanism of IL-1R was not yet known. The *Drosophila melanogaster* Toll receptor was discovered in the 1980s, where Toll, a mutant gene was shown to be critical in *Drosophila* embryonic development (Stein, Roth, Vogelsang, & Nusslein-Volhard, 1991). The Toll gene was cloned in 1988 and was shown to encode a transmembrane receptor with the presence of an intracytoplasmic domain with marked similarities to that of the IL-1R, and is referred as Toll/IL-1R receptor domain (TIR). While the IL-1R consists of a Ig-like domain in their ectodomain and an intracellular TIR domain, the ectodomain of Toll consists of characteristic leucine rich motifs (LRRs) (Imler & Hoffmann, 2002). Thus, each mammalian TLR is composed of an ectodomain with LRRs, which facilitates interactions with PAMPs, and a transmembrane domain responsible for downstream signaling activation. To date, ten functional mammalian TLRs are classified in humans (TLR1–10), and 13 TLRs in mouse (TLR1–9 and TLR11–13) (Takeda & Akira, 2005, 2015). Although nearly all the TLRs share common pathways, they differ greatly with the type of agonists that activate them, and in several characteristics of the subsequent immune and inflammatory response. Table 1 enlists the known human TLRs with their respective pathways and known endogenous and synthetic agonists.

### 2.1. TLR signaling pathways

TLRs recognize PAMPs or DAMPs, and this event results in the activation of signaling pathways for the induction of cytokines, chemokines, and co-stimulatory molecules. Upon engagement of TLRs by PAMPs or DAMPs, TLRs hetero or homo dimerize, which further brings a conformational change in the TIR domain allowing the recruitment of

cytoplasmic adapter proteins. Individual TLRs selectively recruit an explicit set of TIR domain adapter proteins. Myeloid differentiation primary response protein MyD88 (MyD88), TIR domain containing adaptor protein (TIRAP, MAL), TIR-domain-containing adapter-inducing interferon- $\beta$  (TRIF, TICAM1) and TRAM are the four adapter proteins that are identified to anchor the TIR domain (Takeda & Akira, 2005). However, based on the preferences of the TIR domain adapter protein, TLR signaling can be broadly classified in two distinct categories, the MyD88-dependent, which is utilized by all the TLRs except TLR3, and the MyD88-independent pathway or the TIR-domain-containing adapter-inducing interferon- $\beta$  dependent (TRIF) pathway. This selection of MyD88 and TRIF leads to the activation of distinct signaling pathways. For example, the MyD88-dependent pathway activates NF- $\kappa$ B and Mitogen Activated Protein (MAP) kinases for the induction of the inflammatory cytokines genes, while the TRIF-dependent pathway leads to the activation of IRF3, NF- $\kappa$ B and MAPKs for induction of type I interferon and inflammatory cytokine genes (Fig. 1) (Akira, Uematsu, & Takeuchi, 2006). The adapter protein TIRAP recruits MyD88 to the TLR2 and TLR4 at the plasma membrane and at the endosome for TLR9, whereas TRAM recruits TRIF to the TLR4 and results in the activation of the IRF3 (Barton & Kagan, 2009; Kawasaki & Kawai, 2014). Moreover, a number of molecules also negatively regulate TLR signaling. Molecules like Suppressor of cytokine signaling 1 (SOCS1) and casitas B-lineage lymphoma-b (Cbl-b), in combination with tyrosine kinase Syk, act on the MyD88 dependent pathway, while sterile  $\alpha$ - and armadillo-motif-containing protein (SARM) and its splice variant TAG negatively influence the TRIF-dependent pathway (Han et al., 2010; Mansell et al., 2006; Palsson-McDermott et al., 2009; Peng et al., 2010).

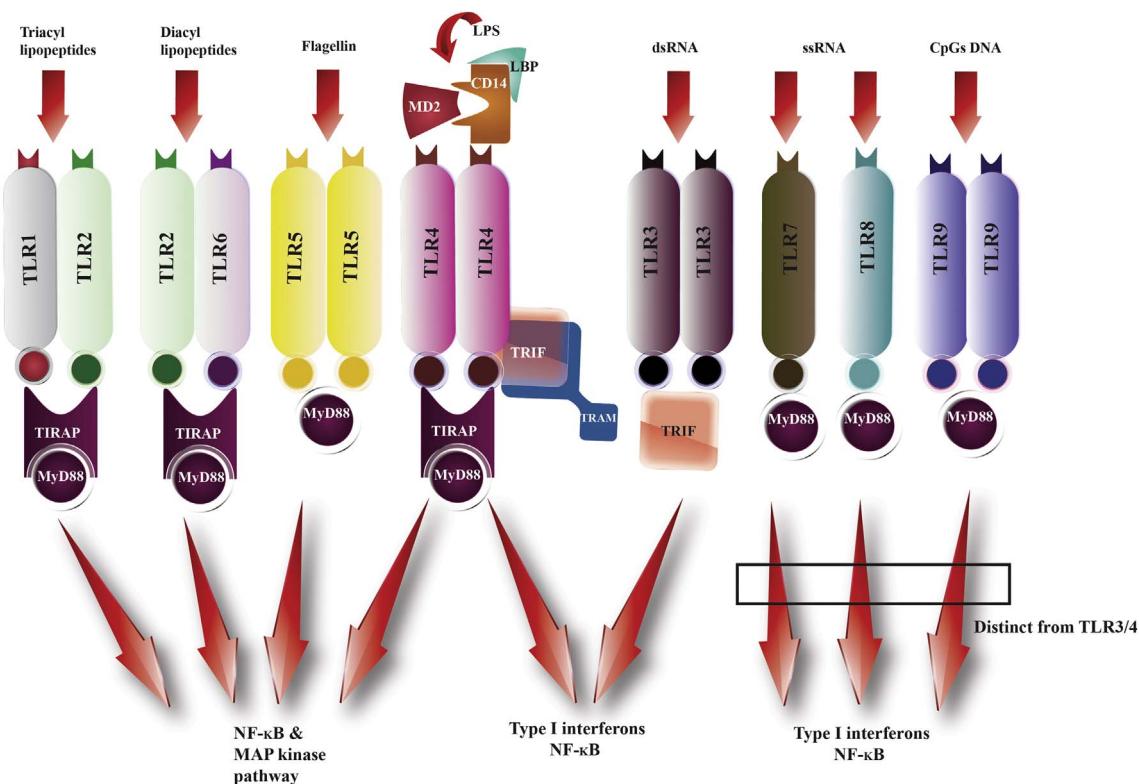

## 3. Nuclear factor $\kappa$ B (NF- $\kappa$ B) proteins and their regulation

NF- $\kappa$ B was discovered in 1986 (Sen & Baltimore, 1986b), as one of the few nuclear transcription factors capable of binding to both the heavy and the kappa ( $\kappa$ ) light chain enhancers in B cells. Of these factors, NF- $\kappa$ B was found to bind only to the  $\kappa$  light chain enhancer. In the subsequent decades, it was established that NF- $\kappa$ B not only was a regulator of B cell development (Baeuerle & Baltimore, 1988; Sen & Baltimore, 1986a), but was also found in the cytoplasm of virtually all cells, and in all animals from *Drosophila* to humans.

In mammalian cells, there are five known NF- $\kappa$ B family members, RelA (p65), RelB, c-Rel, p50/p105 (NF- $\kappa$ B1) and p52/p100 (NF- $\kappa$ B2) (Ghosh, May, & Kopp, 1998; Gilmore, 2006). These proteins interact combinatorically to form a family of homodimers and heterodimers that constitute the transcriptionally active proteins binding to the 9–10 base pair highly variable DNA sites, also known as  $\kappa$ B sites, (50-GG-GRNWYYCC-30; R, A or G; N, any nucleotide; W, A or T; Y, C or T). All five of the NF- $\kappa$ B family members share a characteristic highly conserved amino-terminal Rel homology domain (RHD), which contains a nuclear localization sequence (NLS) and is responsible for dimerization, nuclear translocation, DNA-binding, and interaction with inhibitory IkB

**Table 1**  
Human Toll like receptors, cellular localization, and ligands.

TLR	Cellular localization	Pathway	Endogenous ligands	Synthetic ligands
TLR1–2	Surface	MyD88	Not Known	Pam3CSK4
TLR2	Surface	MyD88	Not Known	MALP-2, Pam2Cys, FSL-1, Hib-OMPC, CFA
TLR3	Endosome	TRIF	Not Known	Poly I:C, poly A:U
TLR4	Surface or endosome	MyD88 or TRIF	Hsp60, Hsp70, fibronectin domain A, surfactant protein A, hyaluronan, HMGB-1	AGP, MPL A, RC-529, MDF2 $\beta$ , CFA
TLR5	Surface	MyD88	Not known	Flagellin
TLR2–6	Surface	MyD88	Not Known	MALP-2 Pam2Cys, FSL-1
TLR7	Endosome	MyD88	Human RNA	Guanosine analogs, imidazoquinolines
TLR8	Endosome	MyD88	Human RNA	Imidazoquinolines, Loxoribine, ssPolyU 3M-012
TLR9	Endosome	MyD88	Human DNA/chromatin	CpG-oligonucleotides
TLR10	Not Known	Not Known	Not Known	Not Known

**Fig. 1.** Schematic of TLR signaling pathways. TLRs differentially recruit specific sets of TIR domain-containing adaptor molecules like MyD88, TRIF, TIRAP/MAL, or TRAM. The MyD88-dependent pathway is utilized by all TLRs except TLR3, where TLR1–2 dimers, TLR2–6 dimers, or TLR5 and TLR4 self-dimerization lead to the activation of NF-κB and MAPKs for the induction of inflammatory cytokine genes. TLR3 utilizes TRIF adapter molecules and leads to the activation of IRF3, NF-κB, and MAPKs for induction of type I IFNs and inflammatory cytokine genes.

proteins.

The synthesis of each NF-κB family member is a highly regulated process. NF-κB1 and NF-κB2 are synthesized as large precursors, p105 and p100, that are post-translationally processed to DNA-binding subunits p50 and p52, respectively (Serasanambati & Chilakapati, 2016). Both p50 and p52 lack a transcription activation domain, but they have a DNA binding domain. However, these proteins can form hetero-dimers with the RelA, RelB, and c-Rel, which have the transcription activation domain. Thus, the NF-κB protein homo- and hetero-dimers regulate target gene transcription differentially, that in turn contributes to the specificity of biological responses (L.-F. Chen & Greene, 2004). For instance, p50 and p52 homodimers function as repressors of NF-κB specific transcription (Ghosh et al., 1998), whereas the heterodimers that contain RelA or c-Rel are transcriptional activators. RelB does not form homodimers but it forms stable heterodimers with either p50 or p52 (Vu, Huang, Vemu, & Ghosh, 2013), which exhibit a greater regulatory flexibility, and can function as both an activator and repressor (Fusco et al., 2009; Marienfeld et al., 2003; Rysack et al., 1992). Following nuclear translocation, the NF-κB dimer binds to the 10-basepair DNA binding sites, which have a great amount of target gene (Kawai & Akira, 2007).

NF-κB1 and NF-κB2 precursor proteins have long C-terminal domains that contain multiple copies of ankyrin repeats, which act as sites for protein-protein interaction, to inhibit these proteins. Similarly, the inhibitory IκB proteins are characterized by the presence of 6 or 7 ankyrin repeats to mediate protein-protein interactions, which binds to the RHD of p65 and masks the nuclear localization sequence, causing sequestration of NF-κB in the cytoplasm (F. E. Chen & Ghosh, 1999; Grimm & Baeuerle, 1993). The IκB family consists of seven members: IκBα, IκBβ, IκBγ, IκBε, Bcl-3, IκBζ and IκBNS. Of these, four members (IκBα, IκBβ, IκBγ, and IκBε) interact with the NF-κB in the cytoplasm to inhibit nuclear translocation of NF-κB, and the remaining three

members (Bcl-3, IκBζ, and IκBNS) are present in the nucleus and interact with NF-κB to regulate transcription (Kawai & Akira, 2007). The nuclear translocation of NF-κB is regulated by interaction with IκB proteins through phosphorylation and proteasome degradation mediated by the IκB kinase (IKK) complex (Karin, 1999). The IKK complex is composed of three subunits: IKKα, IKKβ, and IKKγ. The two catalytic subunits, IKKα (IKK1) and IKKβ (IKK2) contain the kinase domain, a ubiquitin-like domain (ULD) and α-helical scaffold/dimerization domain (SDD), and the third subunit, IKKγ/NEMO (NF-κB essential modulator), is the regulatory subunit, which consists of a coiled coil (CC) domain and a leucine zipper (LZ) domain, responsible for regulating the interaction of the two catalytic subunits through their NEMO-binding domain (NBD). Thus, activation of the NF-κB pathway typically involves the stimulus-mediated phosphorylation of an IκB member primarily by the IKK (IκB kinase) complex. The phosphorylated IκB then undergoes ubiquitination and subsequently proteasome dependent proteolysis, leading to the release and translocation of NF-κB into the nucleus, where it affects gene transcription.

NF-κB activation is mediated through either the canonical (classic) or the non-canonical (non-classic, alternative) pathways, leading to specific activation of subunits and thus producing a specific genetic response (Brasier, 2006). The canonical pathway is crucial for the activation of innate immunity and inflammation signaling, and inhibition of apoptosis. Activation of cell surface receptors or intracellular stress signals proinflammatory cytokines, such as TNFα, IL-1, leading to the activation of the IKK complex. The activated IKK complex, predominantly acting through the signalsome (consisting of IKKα, IKKβ and NEMO), catalyzes phosphorylation of IκBα (at sites Ser32 and Ser36), followed by polyubiquitination and subsequent degradation of this inhibitor in the cytoplasm by the 26S proteasome complex. The degradation of IκBα results in release of NF-κB dimers (p50:RelA dimer) and unmasks the nuclear localization signal in RelA, resulting in rapid

translocation of the NF-κB heterodimer to the nucleus, where it binds to DNA to activate gene transcription (Ghosh & Hayden, 2012).

The alternative pathway is mainly involved in lymphoid organogenesis as well as B-cell survival and maintenance, under normal physiological conditions. Aberrant activation of this pathway is involved in human malignancies, auto-immunity and metabolic diseases (Brasier, 2006; Keats et al., 2007). In the alternative pathway, the stimulus dependent activation of NF-κB heterodimer (p52:RelB) is dependent on IKK $\alpha$ , which is induced by the NF-κB-inducing kinase (NIK), a mitogen-associated protein 3 kinase (MAP3K) originally thought to mediate NF-κB activation by cytokines including TNF- $\alpha$  and IL-1 (Sun, 2011). Upon phosphorylation by NIK, activated IKK $\alpha$  further phosphorylates p100 at two C-terminal sites, followed by its ubiquitination and proteasomal processing to p52 (Chen & Greene, 2004). In contrast to the p50-RelA heterodimers of the canonical pathway, the non-canonical pathway involves creation of transcriptionally competent NF-κB heterodimer, p52/RelB complexes that translocate to the nucleus and induce target gene expression (Cildir, Low, & Tergaonkar, 2016). Notably, while both IKK $\beta$  and NEMO are essential in the canonical pathway, noncanonical NF-κB signaling does not require these IKK components, but instead requires IKK $\alpha$  and NIK. NIK protein levels are critically regulated under normal cellular environment by continuous degradation by TRAF3 E3 ubiquitin ligase complex, comprising of TRAF3, TRAF2, and cellular inhibitor of apoptosis 1 and 2 (cIAP1/2). Upon stimulation, TRAF3 is degraded leading to NIK stabilization and accumulation. As a negative regulatory mechanism, NIK can also be phosphorylated by IKK $\alpha$  or T-ANK-Binding Kinase 1 (TBK1) and degraded to limit the activation of the pathway under different conditions.

Typically, the canonical pathway is involved in the rapid immune response towards inflammation or in response to pathogens, and the non-canonical pathway is activated through slow developmental signals. Although, both the canonical and non-canonical pathways were generally thought to occur in response to independent signaling mechanisms, and respond to separate physiological conditions, recently crosstalk interactions have been reported interconnecting the two pathways (Shih, Tsui, Caldwell, & Hoffmann, 2011). This crosstalk involves expression control of NF-κB monomers, interdependent proteolytic processing of precursors, and interrelated regulatory mechanisms (Cildir et al., 2016). One example is the newly identified IκB $\delta$  activity that is enhanced by one pathway and disrupted by the other (Shih et al., 2011).

#### 4. Expression and function of TLRs in non-infectious lung diseases

The expression of TLRs is not restricted to antigen processing and presenting cell types. Rather, TLR expression is detected in various cell populations and tissue types (Iqbal, Philbin, & Smith, 2005). In the lung, TLRs are widely expressed on resident cells such as alveolar macrophages, and infiltrating cells of myeloid and lymphoid origin. Human and animal studies have also reported high levels of expression of nearly all the TLRs in the lung (Muir et al., 2004; Tirumurugaan et al., 2010; Zaremba & Godowski, 2002). TLRs are widely researched in infectious lung diseases, where a number of TLRs were found to be associated with pathogen clearance by amplifying immune responses (Abel et al., 2002; Albiger et al., 2007; Biondo et al., 2005; Chai et al., 2011; Eder et al., 2004; Krutzik & Modlin, 2004; Yoshimura et al., 1999). In the context of non-infectious lung diseases, limited studies have been done, however they indicate strong and pharmacologically important involvement of TLRs, especially in inflammatory processes activated by exposure to ambient air pollution and cigarette smoke (Bauer, Diaz-Sanchez, & Jaspers, 2012).

The severity and degree of allergic asthma exacerbations has been associated with environmental factors such as allergens, but is also dependent on allergen type, duration, degree of exposure, and the patient's overall health and genetics. Studies have identified several susceptible genes that contribute to the onset of allergic asthma, and the

overall disease progression (Ober & Yao, 2011). Among these, a predominant role of TLRs and their polymorphisms (in particular TLR2, TLR4 and TLR7, TLR8 and TLR9) has been implicated in the physiopathology of asthma (Lazarus et al., 2003; Noguchi et al., 2004; Reijmerink et al., 2010; Tesse, Pandey, & Kabesch, 2011; Vercelli, 2008). Along with polymorphic variation in the TLR genes, genetic variation in regulatory and intracellular molecules involved in TLR signaling pathways are also known to exhibit functions in allergic asthma onset and exacerbations. In this regard, evolutionary genetic studies have suggested a genetic predisposition in human TLR-related pathway genes, such as IL1RL1, BPI, NOD1, NOD2 and MAP3K7IP1 with the development of asthma (Eder et al., 2004; Casanova, Abel, & Quintana-Murci, 2011).

#### 5. Activators of NF-κB in noninfectious lung diseases

In the past decades, multiple studies have demonstrated that NF-κB is vigorously involved in a myriad of mechanisms. Thus, the name "central switch" justifies its role in the regulation of expression of over 300 genes in a cell-specific and stimulus-specific manner (Pahl, 1999; Thanos & Maniatis, 1995). This broad spectrum of regulatory activities of NF-κB ranges from normal cell physiological processes (O'Neill & Kaltschmidt, 1997), inflammation (Baeuerle & Baichwal, 1997), infection (Hiscott, Kwon, & Génin, 2001), metabolism of ROS (Turillazzi et al., 2016) and DNA damage, to cancer and auto immune diseases (Davoudi et al., 2014; De Simone et al., 2015).

In addition to the physiological stress caused by infectious diseases, the human body is also exposed to environmental hazards and therapeutic drugs, which lead to non-infectious stress. Due to the exposure of the respiratory system to the environment, the lung is vulnerable to infectious agents causing acute pulmonary diseases and noninfectious chronic lung diseases, such as asthma, bronchopulmonary dysplasia, and chronic obstructive pulmonary disease (Parker & Prince, 2011). However, infectious agents play a role in chronic lung diseases in addition to acute pulmonary diseases and contribute to worsening of airflow obstruction and/or lung parenchymal damage. As airway injury persists due to allergen exposure, smoke, or other environmental irritants such as ozone ( $O_3$ ) and  $NO_2$ , it causes not only impairment of innate immunity, but also increased susceptibility of the lower respiratory tract to pathogens (Bochkov et al., 2010; Iwasaki & Medzhitov, 2010; Opitz, van Laak, Eitel, & Suttorp, 2010). These non-infectious stress conditions lead to the amplification of inflammatory pathways that are critical to the host defense. This is the case of chronic obstructive pulmonary disease (COPD) and asthma, as well as other chronic inflammatory diseases. The inflammatory response in the airway is associated with symptoms such as mucus secretion, plasma exudation, bronchoconstriction, and airway hyperresponsiveness. The inflammatory immune response in asthma only differs in severity and longevity, but not in effect, in comparison to the response against infectious agents, as the immune response persists as long as the allergen exposure continues.

Airway inflammation is one of the central features of COPD and asthma. Exacerbations of COPD are associated with elevated airway levels of proinflammatory mediators, and there have been important advances in understanding the underlying inflammatory processes in the past decade (Iwasaki & Medzhitov, 2004; Rahman, Gilmour, Jimenez, & MacNee, 2002; Rom, Avezov, Aizenbud, & Reznick, 2013). Many inflammatory cells are involved in airway inflammation, and a large number of inflammatory mediators such as cytokines, chemokines, enzymes, receptors and adhesion molecules have been identified as key players (Huertas & Palange, 2011). Inflammatory mediators play a crucial role in the chronic inflammatory process, as they appear to determine the nature of the inflammatory response by directing the selective recruitment and activation of inflammatory cells, such as eosinophils, T-lymphocytes, mast cells, DCs, and macrophages (Fischer, Pavlisko, & Voynow, 2011). Moreover, in addition to the inflammatory

cells, structural cells of the airways, such as epithelial cells, fibroblasts, airway smooth muscle cells, and endothelial cells, also release inflammatory mediators. These mediators perpetuate the inflammatory response within the airways by further increasing the expression of inducible genes that encode inflammatory proteins. These inducible genes are regulated by transcription factors, which are activated in response to various stimuli and bind to the promoter region of the inflammatory genes to increase their rate of transcription. One such transcription factor is NF- $\kappa$ B, which is activated in response to release of pro-inflammatory cytokines, viruses, activators of protein kinase C (PKC), and in response to environmental stress, such as exposure to heavy metals, reactive oxygen intermediates, cigarette smoke and by various therapeutic drugs, including chemotherapeutic agents.

## 6. TLRs and NF- $\kappa$ B in allergic asthma: effects on epithelial and immune cell function

TLRs are expressed in a variety of airway cells including epithelial cells, macrophages, mast cells, and DCs. Stimulation of TLRs by infectious agents activates antigen presenting cells (APC), and control T helper (Th1, Th2, and Th17) immune cell differentiation in a context-dependent manner, along with activation of mast cells for cytokine production (Pulendran et al., 2001). During allergic airway inflammation, engagement of TLRs on DCs favors Th2 polarization and eosinophilia, a characteristic of allergic lung diseases. However, studies have reported Th17 response driven neutrophilic airway inflammation in asthmatics with poor response to inhaled glucocorticoids, which primarily target eosinophilic inflammation (Barczyk, Pierzchala, & Sozanska, 2003; Bullens et al., 2006; McGrath et al., 2012). Cumulatively, the selection of Th2 or Th17 responses depends on factors including response of different airway cell types to different allergens, and recruitment of TLRs with specific sets of TIR domain adapter proteins. Classically, during Th2 responses, DCs play a very important role by activating allergen-specific Th2 cells and inducing their proliferation, leading to the release of a particular set of cytokines, emergence of helper functions and generation of memory cells. Regardless of site, neutrophilic inflammation tends to show a direct relationship with lipopolysaccharides (LPS) exposure, a major component of the outer cell wall of Gram-negative bacteria, by activation of the Th17 response with the assistance of DCs (McAleer et al., 2010; Wang et al., 2012; Wilson et al., 2009). Importantly, TLR2 and TLR4 are highly expressed in cells exposed to LPS, where TLR4 is the only known TLR that can signal through both MYD88 and TRIF-dependent pathways. Interestingly, animal studies have shown that LPS-induced MYD88-dependent TLR4 activation leads to Th2 response activation and asthma, whereas TRIF-dependent activation of TLR4 leads to Th17 response and neutrophilia (Hsia et al., 2015; Piggott et al., 2005). Furthermore, a recent study by McAlees et al. showed variation in the response to a same set of allergens among different lung cell types. These investigators found that TLR4 expression in airway epithelial cells exposed to LPS support eosinophilic airway inflammation, whereas TLR4 expression by hematopoietic cells was essential for Th17-driven neutrophilic airway inflammation (McAlees et al., 2015).

Taken together, these studies raise important questions about the mechanisms underlying eosinophilic and neutrophilic airway inflammation in asthma, and more importantly, how different lung cell types and their structural and molecular milieu behave when exposed to different sets of allergens. In the following section, we will further focus on the role of TLRs and NF- $\kappa$ B in different airway cell types during allergic asthma exacerbations.

### 6.1. TLRs and NF- $\kappa$ B in airway epithelial cells

Respiratory epithelial cells form the first line of defense against dust, microorganisms, gases and allergens. These cells form a highly regulated and impermeable barrier through the formation of tight

junctions and adherent junction proteins, which may lead to epithelial barrier dysfunction upon repeated exacerbations and insults. Both the human bronchus epithelial cell line BEAS-2B and primary airway epithelial cells are reported to express all the TLRs with the exception of TLR8 in BEAS-2B cells (Ioannidis, Ye, McNally, Willette, & Flano, 2013; Mayer et al., 2007; Muir et al., 2004; Platz et al., 2004; Sha, Truong-Tran, Pitt, Beck, & Schleimer, 2004). Further studies on the distribution of TLRs shed light on the importance of the integrity of the lung endothelial barrier system, as TLR3 was reported to be distributed on both apical and basolateral surfaces, TLR2 and TLR6 mostly on basolateral, and TLR1, TLR4, TLR5, TLR7, TLR9 and TLR10 were reported to have luminal distribution on airway epithelial cells (Ioannidis et al., 2013). Nevertheless, the majority of these studies were performed on airway epithelial cells from healthy individuals, or non-asthmatic patients. Furthermore, it is worth noting that the airway epithelium of asthmatics is reported to have increased shedding and mucin production, and the compromise in the integrity and stress on airway epithelium is further augmented with increased activation of nuclear factor- $\kappa$ B (NF- $\kappa$ B), increased expression of heat-shock proteins, AP-1 and other transcription factors (Holgate et al., 2003). This leads an open debate on the offerings of TLRs in conjunction with airway epithelial cells in the pathophysiology of asthma. Infection on the lung epithelium tends to increase the production of pro-inflammatory mediators such as IL-6, IL-8, Chemokine (C-C motif) ligand 5 (CCL5), Tumor necrosis factor (TNF) and type I IFNs (Interferon), which can further promote advance adaptive immune responses. Studies on the intestinal epithelium and dermal micro-vessel endothelial cells portray an opposite phenomenon and tend to limit inflammatory responses to infection by expressing TLR-attenuating molecules like toll/interleukin-1 resistance family member, TIR8, and transforming growth factor- $\beta$  (Garlanda et al., 2004; Naiki et al., 2005).

Allergic asthma is triggered by multiple specific and non-specific stimuli, where bronchial epithelial cells produce a variety of cytokines and chemokines that aid in the recruitment of inflammatory cells and antigen presenting cells to the airways. Remarkably, NF- $\kappa$ B regulates the expression of many of these pro-inflammatory mediators, adhesion molecules, respiratory mucins, and growth and angiogenic factors. In 1997, Stacey et al. reported for the first time that primary cultures of bronchial epithelial cells of asthmatic patients who were allergic to house dust mites, resulted in NF- $\kappa$ B activation when exposed to Der p1 (the major allergen from mite, *Dermatophagoides Pteronyssinus*) (Stacey et al., 1997). In another study, receptors for advanced glycation end-products (RAGE), the cell-surface receptors expressed by alveolar type I (ATI) epithelial cells, were upregulated by diesel particulate matter (DPM) in ATI cells, as shown by RAGE mRNA and protein synthesis (Reynolds, Wasley, & Allison, 2011). Furthermore, both DPM-induced activation of NF- $\kappa$ B and the secretion of two NF- $\kappa$ B targets, IL-8 and MCP-1, were significantly influenced by RAGE signaling. Rahman et al. later explored the effect of oxidative stress and the pro-inflammatory mediator TNF- $\alpha$ , on histone acetylation/deacetylation and activation of NF- $\kappa$ B and AP-1, leading to the release of the pro-inflammatory cytokine IL-8 in human alveolar epithelial cells (A549) (Rahman et al., 2002).

Furthermore, very strong advocating evidence for the involvement of TLRs in the progression of asthma arose from the studies on Thymic stromal lymphoprotein (TSLP). TSLP, an IL-7-like cytokine which is mainly expressed by lung epithelial cells, has been shown to activate DCs and prime the Th2 cell response along with playing a crucial role in the maintenance of Th2 central memory cells (Y. J. Liu, 2006; Wang et al., 2006; Zhou et al., 2005; Ziegler & Liu, 2006). Upon activation of DCs, TSLP also promotes the expression of mRNA for the Th2 attracting chemokine CCL17 (Y. J. Liu, 2006), known for its properties to accelerate pulmonary fibrosis (Belperio et al., 2004). In addition, the increased expression of TSLP induces chemotaxis like eotaxin-2 for eosinophils and IL8 for neutrophils (Y. J. Liu, 2006). Finally, strong evidence for involvement of TLRs in asthma inflammation and

progression is coming from bacterial (TLR2 and TLR9) and viral (TLR3 and TLR8) models, in which these were found to initiate TSLP expression by epithelial cells (Allakhverdi et al., 2007; Lee & Ziegler, 2007).

## 6.2. TLRs and NF- $\kappa$ B in dendritic cells

As antigen presenting cells that are in close contact with the airway epithelium, DCs are crucial in determining the outcome of allergen encounters in the lung. In addition, epithelial cell derived mediators can influence the DC function on T cells polarization. Anatomically, DCs form a dense network above and beneath the respiratory epithelium and extend their dendrites through the epithelial layer to sample the luminal environment. Lung DCs exist in an immature state, where they recognize and capture inhaled foreign antigens (Cella, Sallusto, & Lanzavecchia, 1997), and undergo maturation prior to migrating to draining lymph nodes where they activate the naïve T cells. The migration of DCs to draining lymph nodes increases considerably in response to inflammatory signals. However, the activation of naïve T cells requires maturation of DCs, which in turn require an array of appropriate signals from the ingested foreign antigen. Fully mature DCs exhibit high surface expression of the major histocompatibility complex (MHC) and costimulatory molecules that influence both innate and adaptive immune responses. In contrast, immature DCs cannot activate naïve T cells and induce immunogenic tolerance to antigens. This functional heterogeneity among lung DCs is crucial for the regulation of tolerogenic or inflammatory responses against inhaled antigens.

The process of DC maturation involves direct signals derived from receptor-mediated antigen uptake, and accessory signals from the host PAMPs or DAMPs recognition through PRRs. Lung DCs exhibit an array of surface and intracellular PRRs, including TLRs, nucleotide-binding domain/leucine-rich repeat receptors, C-type lectin receptors and a variety of other receptor molecules which differ considerably among different human lung DC subsets (Demets, Brusselle, Vermaelen, & Pauwels, 2005; Masten et al., 2006; Schlecht et al., 2004). Among the most widely studied human lung DC subsets are the myeloid DC type 1 (mDC1, expressing BDCA1 and MHCII), myeloid DC type 2 (mDC2, expressing BDCA3 and MHCII), and plasmacytoid DC (pDC, expressing BDCA2 and CD123) (Demets et al., 2005). The expression pattern of TLRs among these three DC subsets varies considerably. While mDC1 and mDC2 cells exhibit presence of TLR1–4, TLR6 and TLR8, pDCs differ greatly to the other two DC subsets with expression of TLR1, TLR6–7 and TLR9 (Demets et al., 2005; Masten et al., 2006; Schlecht et al., 2004). The TLR9 expression by pDCs is unique, as the B cells are the only other human cells known to express TLR7 and TLR9 (Fuchsberger, Hochrein, & O'Keeffe, 2005). Notably, naïve pDCs are known to express very low quantities of TLR4 (Castellaneta, Sumpter, Chen, Tokita, & Thomson, 2009). This marked variation in the expression pattern of PRRs, in particular of TLRs, in pDCs is of high importance as pDCs have been implicated in mechanisms of tolerance induction to the inhaled antigens. Direct evidence for the involvement of pDCs and TLRs in asthma is coming from animal studies evaluating Treg cells. These studies indicate involvement of two types of Treg cells in the suppression of asthmatic lung inflammation: the natural or thymic-derived Foxp3+ Treg (nTreg) cells, and the inducible Treg (iTreg) cells that develop in the periphery in response to antigen exposure (Curotto de Lafaille et al., 2008; Duan, So, & Croft, 2008; Ostroukhova et al., 2004). Interestingly, iTreg cells are induced and prevail when mice are exposed to pure protein antigens, whereas CD4+ T cells are primarily induced with fewer iTreg cells when mice are exposed to protein allergens mixed with TLR4 ligands (Castellaneta et al., 2009; Duan et al., 2008; Duan et al., 2010; Duan, So, Mehta, Choi, & Croft, 2011; Sorosh et al., 2013). Furthermore, studies using antibody-based depletion of pDCs during inhalation of inert soluble antigens showed asthma development with characteristic immunoglobulin E sensitization, airway eosinophilia, goblet cell hyperplasia, and Th2 cell cytokine production (de Heer et al., 2004).

The enzymatically active allergens activate protease-activated receptors (PARs) expressed in epithelial cells, an event followed by NF- $\kappa$ B activation and the perpetuation of chemokines and cytokines by epithelial cells that further attract and activate DCs (Lambrecht & Hammad, 2009). The involvement of NF- $\kappa$ B in the control of DC development has been established in earlier studies, in which inhibition of NF- $\kappa$ B activation blocked maturation of DCs in terms of upregulation of MHC and costimulatory molecules (Rescigno, Martino, Sutherland, Gold, & Ricciardi-Castagnoli, 1998). In the case of atopic diseases, in which there is a predominance of Th2 responses to environmental exposures, it is known that pollen-derived allergens are often accompanied by proinflammatory and immunomodulatory lipids, termed pollen-associated lipid mediators (PALMs). These PALMs include E1-phytoprostanes (PPE1), which were identified to modulate dendritic cell (DC) function. PPE1 inhibit the DC's capacity to produce IL-12, and enhance the DC-mediated Th2 polarization of naïve T-cells via PPAR- $\gamma$ -dependent pathways that lead to inhibition of NF- $\kappa$ B activation and result in reduced IL-12 production by DCs and consecutive Th2 polarization (Gilles et al., 2009).

Interestingly, incubation with one of the most commonly used analgesic and antiinflammatory agents (aspirin, a salicylate), reduced neither DC viability nor their number, but changed their surface marker phenotype via suppression of expression of antigen-presenting and costimulatory molecules. This mechanism involved secretion of the p40 subunit of IL-12 and activation of NF- $\kappa$ B (Matasić, Dietz, & Vuk-Pavlović, 2000). In addition, treatment with pharmacologically active concentrations of salicylates markedly reduced the levels of activated NF- $\kappa$ B in DCs without triggering apoptosis, thus inhibiting DC differentiation with the consequent loss of their immunostimulatory function (Hackstein et al., 2001), as similarly observed with other many agents that suppress DC maturation via NF- $\kappa$ B inhibition.

## 6.3. TLRs and NF- $\kappa$ B in eosinophils

Eosinophils are considered one of the most important cell types involved in the pathobiology of asthma. As early as the 1920s, postmortem studies of asthmatics revealed hyper-inflated lungs showing desquamated lung epithelial cells and massive infiltration of eosinophils and neutrophils in the airway mucosa (Cardell & Pearson, 1959; Huber & Koessler, 1922). Subsequent experimental animal studies, and studies with human lung biopsies also indicated increased infiltration of eosinophils in asthmatics, however their function in asthma development and severity remained largely elusive (Beasley, Roche, Roberts, & Holgate, 1989; Bradding et al., 1994; Hogan et al., 1998; Hogan et al., 2008). Many different molecules including IL-3, IL-4, IL-5, IL-13, and GM-CSF are known to activate eosinophils to release various chemokine and cytokine mediators including TGF- $\beta$ , IL-5, IL-3, IL-4 and IL-13 (Bradding, Feather, Wilson, Holgate, & Howarth, 1995; Bruijnzeel et al., 1992; Dubucquoi et al., 1994; Schmid-Grendelmeier et al., 2002). It has been proposed that these mediators play a dynamic role in asthma airway modulation and disease progression. Out of many mediators, the Th2 cell-associated cytokine IL-5 has a crucial impact on eosinophils. A very strong evidence came from a study by Sehmi et al. on the contribution of the hematopoietic progenitor cells in allergic airway diseases. In this study, the authors demonstrated that atopic asthmatic subjects had large numbers of eosinophil/basophil progenitor cells expressing IL-5 receptor alpha in the bone marrow, and when these progenitor cells were cultured with IL-5 ex vivo, they developed into eosinophils (Sehmi et al., 1996). Another convincing study in which anti-IL-5 was administered to asthmatics in a double-blind placebo-controlled trial, demonstrated a significant reduction in airway remodeling and BAL eosinophil counts, despite no significant improvement in asthma symptoms (Flood-Page et al., 2003).

Like many other myeloid innate immune cells, eosinophils exhibit various PRRs, including TLRs (Mansson & Cardell, 2009; Nagase et al., 2003; O'Flaherty et al., 2017; Porsbjerg, Baines, Sverrild,

Backer, & Gibson, 2014; Sabroe, Jones, Usher, Whyte, & Dower, 2002; Wong, Cheung, Ip, & Lam, 2007), nucleotide-binding domain/leucine-rich repeat receptors (Kvarnhammar, Petterson, & Cardell, 2011), and C-type lectin receptors (Acharya & Ackerman, 2014; Willment et al., 2005; Yoon, Ponikau, Lawrence, & Kita, 2008). Upon PRRs-assisted activation, they also secrete cytokines and chemokines for activation of other immune cells. Among the TLRs expressed in eosinophils, significant levels of TLR1–2, TLR4–7 and TLR9 are expressed constitutively. However, a few studies have also find expression of TLR3 mRNA and protein in eosinophils from bone marrow and peripheral blood (Kvarnhammar & Cardell, 2012). Studies with TLR agonists have indicated varied but strong associations of eosinophils with allergic asthma development and progression. In an animal model, TLR7 and TLR9 agonists not only were shown to diminish airway eosinophilia in a dose-dependent manner, but also to reduce levels of IL-4 and IL-5, while TLR2 and TLR4 agonists were found to promote eosinophilia (Duechs et al., 2011). Contrasting findings from other researchers, however, indicated beneficial effects of TLR2 and TLR4 stimulation in allergic asthma (Akdis et al., 2003; Taylor, Richmond, & Upham, 2006). Therefore, further investigation is required to determine whether TLRs play favorable or adverse effects in eosinophils during allergic asthma.

Asthmatics show a characteristic accumulation and persistence of eosinophils in their lungs (Vignola et al., 2000). Studies have demonstrated that apoptosis of lung eosinophils is considerably delayed in asthmatic patients in comparison to healthy individuals (Ilmarinen & Kankaanranta, 2014). Yang et al. have also reported that mice deficient in the p50 subunit of NF- $\kappa$ B are incapable of mounting eosinophilic airway inflammatory responses, and have decreased IL-5 and chemokine-eotaxin gene expression when compared to wild-type mice; both of which are key mediators of eosinophilic inflammation in the airways (Yang et al., 1998). Correspondingly, Das et al. observed that p50-deficient mice have reduced eosinophilic responses to aerosolized allergens due to lack of production of Th2 cytokines, IL-13, IL-4 and IL-5 (Das et al., 2001). Similarly, c-Rel knockout mice, an allergen-induced asthma model, have decreased airway hyper-responsiveness and eosinophil infiltration as well as lower levels of serum IgE when compared to wild-type mice (Donovan et al., 1999). Treatment with NF- $\kappa$ B inhibitors such as MG-132, a peptide aldehyde type of proteasome inhibitor, is reported to reduce the number of eosinophils and decrease allergic inflammation (Edwards et al., 2009). Together, these observations support the notion that NF- $\kappa$ B is a central inflammatory factor in severe eosinophilic asthma, and can be used as a potential therapeutic target to prevent eosinophilia.

## 7. TLRs, NF- $\kappa$ B and lung oxidative biology

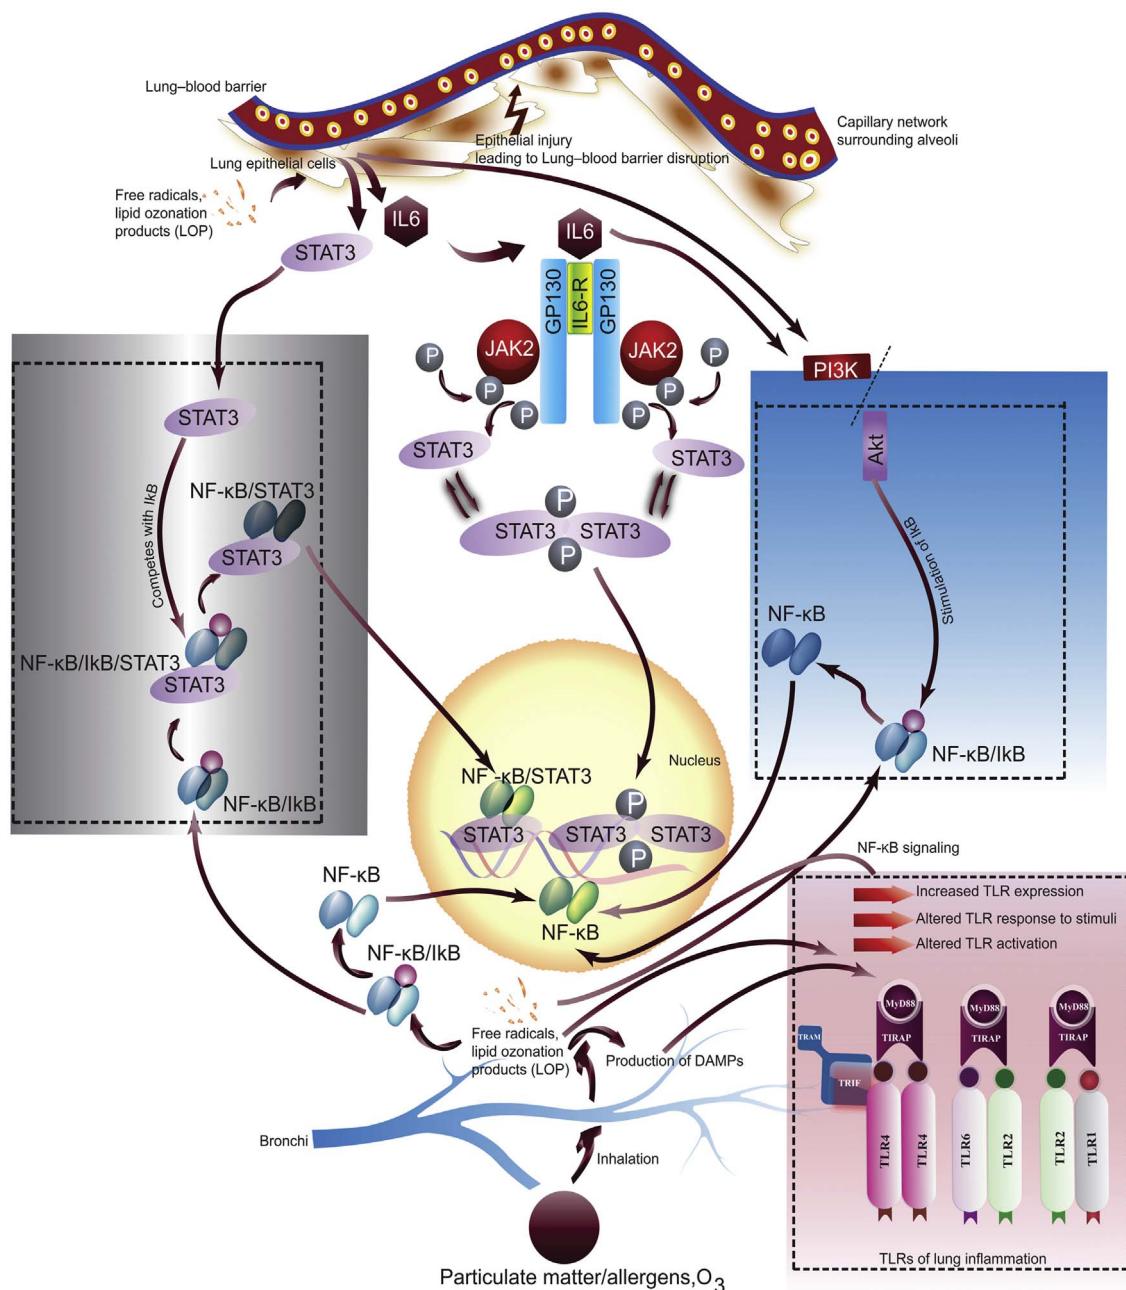

The imbalance between oxidants like reactive oxygen species (ROS) and reactive nitrogen species (RNS) and antioxidants in favor of oxidants, is being termed as oxidative stress, a condition known to result in biological damage. Although, generation of oxidative molecules is part of the normal metabolism, the intracellular levels of ROS and RNS are maintained at low concentrations under normal physiological conditions (Rahal et al., 2014). The lungs are continuously exposed to a variety of oxidants that differ in type and degree, and can easily overcome the resulting oxidative stress with the help of a network of existing enzymatic and non-enzymatic antioxidants. While airway inflammation and asthma tend to increase the production of ROS and RNS, mostly contributed by eosinophils and neutrophils (Kinnula, 2005; Suzuki et al., 2008), accumulating evidence suggests the involvement of ROS and RNS, and oxidative stress in the genesis and modulation of asthma (Al-Harbi et al., 2015; Comhair & Erzurum, 2010; Erzurum, 2016; Ghosh & Erzurum, 2011, 2012; Jiang et al., 2014; N. Li, Hao, Phalen, Hinds, & Nel, 2003; Riedl & Nel, 2008; Sugiura & Ichinose, 2008; Uchida et al., 2017). Moreover, the effects of potent oxidants, such as cigarette smoke and O<sub>3</sub>, have validated the relationship between TLRs and oxidative stress in the genesis of lung inflammation. In-

vitro studies have shown that inhalation of particulate matter components can stimulate TLR2 and TLR4 (Becker, Fenton, & Soukup, 2002). An interesting correlation between TLRs expression and lung inflammation was observed in studies of O<sub>3</sub> exposure in mice. Kleeberger et al. (Kleeberger, Reddy, Zhang, & Jedlicka, 2000) performed a genome screening of mouse strains susceptible and resistant to O<sub>3</sub> inflammation, and reported an association with a quantitative trait locus on chromosome 4, which contains the candidate gene for TLR4. Furthermore, they observed an increase in TLR4 expression in mice susceptible to O<sub>3</sub> compared to strains resistant to O<sub>3</sub>. Another study by Hollingsworth et al. performed on TLR4-deficient mice reported an involvement of TLR4 in pulmonary inflammation triggered by environmental challenges (LPS, particulate matter, and O<sub>3</sub>), in a toxin and exposure dependent manner (Hollingsworth et al., 2004). Similarly, studies with human bronchial airway epithelial cells and alveolar macrophages exposed to ambient air particulate matter also showed involvement of both TLR2 and TLR4 (Becker, Mundandhara, Devlin, & Madden, 2005). Further corroboration for the involvement of these receptors in lung inflammation was shown by a study on the effects of O<sub>3</sub> exposure on TLR2-, TLR4-, and MyD88-deficient mice, where TLR2, TLR4, and MyD88 were associated with inflammation and airway hyperresponsiveness, and Myd88 was associated with the neutrophilic response to O<sub>3</sub> (Williams et al., 2007). In addition, our group has reported sex differences and a significant upregulation of Myd88 in response to O<sub>3</sub> exposure along with three other genes, Cxcl2, C4b and Ccl9 (Cabello et al., 2015).

Cigarette smoke increases the expression of TLR4 and TLR9 along with cytokine expression on lung CD8<sup>+</sup> T cells (Mortaz et al., 2010; Nadigel et al., 2011). However contrasting results were obtained in a study comparing alveolar macrophages from COPD patients, healthy smokers, and non-smokers, where a decrease in TLR2 expression was also found (Droemann et al., 2005). Several studies have shown that TLRs, and in particular TLR4 contribute significantly to the redox balance of the lung (Cosio, Saetta, & Agusti, 2009; Zhang, Shan, Jiang, Cohn, & Lee, 2006). Using TLR4 and MyD88 knockout mice, Zhang et al. identified TLR4 as an essential factor for lung homeostasis, and its protective effects against oxidative stress through regulation of nicotinamide adenine dinucleotide phosphate-oxidase (NADPH oxidase) activity. Taken together, these studies indicate that oxidant production is associated with different TLRs in different lung cell types.

In the previous section, we have discussed the pathways that lead to the activation of NF- $\kappa$ B. NF- $\kappa$ B is a redox-sensitive transcription factor, and the context dependent activation/inhibition of NF- $\kappa$ B by oxidizing agents has been studied for decades. Notably, the NF- $\kappa$ B canonical or classic pathway relies on activation of the IKK complex, in particular IKK $\beta$ , which in turn dictates the phosphorylation of I $\kappa$ B $\alpha$  to regulate mechanisms of cell proliferation, differentiation, apoptosis, immunity and stress responses (Siomek, 2012). The alternative pathway, in which IKK $\alpha$  is a major player, is important for homeostasis and adaptive immunity; whereas the IKK-independent atypical pathway is mainly triggered in response to hypoxia, reoxygenation, ionizing radiations, and H<sub>2</sub>O<sub>2</sub>.

Depending on the context, ROS can be either harmful or beneficial. ROS have been shown to initiate inflammatory responses in the lung through the activation of transcription factors such as NF- $\kappa$ B resulting in chromatin remodeling and further gene expression of pro-inflammatory mediators (Rahman & MacNee, 1998; Richter et al., 1995). A number of reports have indicated the requirement of ROS for NF- $\kappa$ B activation at various cellular levels and pathways (Bonizzi et al., 1999; Chandel, Schumacker, & Arch, 2001; Hughes, Murphy, & Ledgerwood, 2005; Li & Engelhardt, 2006). However, often ROS exert opposing results with NF- $\kappa$ B activation and inhibition, where ROS stimulates signal transduction pathways for NF- $\kappa$ B at cytoplasmic levels and greatly inhibit DNA binding of NF- $\kappa$ B at the nuclear level (Kabe, Ando, Hirao, Yoshida, & Handa, 2005). Studies on human pulmonary artery endothelial cells have shown that TNF $\alpha$  induces ROS, which in turn

**Fig. 2.** Schematic of oxidative stress induced lung inflammation and role of IL-6 signaling pathways in conjunction with TLRs and NF-κB. Oxidative stress leads to the generation of lipid peroxidation products, ROS, free radicals in lung cell types. These oxidants can further mediate activation of downstream biochemical events including increased and altered TLR expression and activation in response to allergens. Oxidants and oxidative stress also impart direct effect on NF-κB as well as on the molecules of NF-κB pathway leading to the production of inflammatory factors and lung damage. (Adapted and modified from (Mishra et al., 2016)).

signals the activation of NF-κB, that regulates the expression of ICAM-1 and E-selectin genes (Rahman, Bando, Kefer, Anwar, & Malik, 1999; Rahman, Kefer, Bando, Niles, & Malik, 1998). Similarly, studies with NADPH oxidase, which is a main cellular source of ROS in mononuclear and granulocytic leukocytes, have shown that NADPH oxidase-derived ROS can regulate lung inflammation and injury through redox regulation of NF-κB activity (Han et al., 2013; Koay et al., 2001). Our findings with O<sub>3</sub>-induced inflammation showed differential intracellular activation of the JAK2/STAT3 and NF-κB/AKT pathway in a sex-dependent manner, and suggested a potential role of sex hormones in this regulation (Fig. 2) (Mishra, DiAngelo, & Silveyra, 2016). It is noteworthy that AKT can affect IKK regulation, where AKT itself can be context-dependent regulated either positively and negatively by ROS (Lee et al., 2002; Murata et al., 2003).

## 8. Pharmacological approaches targeting TLR/NF-κB and oxidative biology

The standard eosinophilic asthma treatment includes β2-agonists and systemic corticosteroids (Walford & Doherty, 2014). The oral or systemic administration of corticosteroids is known to exert strong effects on leukocyte recruitment (Cronstein, Kimmel, Levin, Martinuk, & Weissmann, 1992), and exhibit very effective anti-inflammatory properties by modulating NF-κB and AP-1 expression (Cronstein et al., 1992; Mittelstadt & Ashwell, 2001). Although treatment with corticosteroids is considered as the gold standard, various studies have reported a significant incidence of adverse effects with high dose and long-term use of corticosteroids (Baraket et al., 2012; Dahl, 2006; Donohue & Ohar, 2004; Geddes, 1992).

Oxidant production by PRRs such as TLRs, or oxidant-based activation of PRRs, can initiate a cascade of events involving redox regulation of transcription factors such as NF- $\kappa$ B. These molecular events share several common pathways and intermediary molecules. Targeting oxidizing molecules in conjunction with PPRs and regulators of transcription factors may present a novel therapeutic strategy for asthma. Considering that ROS and RNS formation, as well as lipid peroxidation products, play key roles in the foundation and further progression of asthma, the use of free radical scavengers and antioxidant stabilizers with multifactorial effects on free radicals, PRRs and regulatory transcription factors may achieve ideal success in treatment. Molecules known to possess antioxidant activity along with ability to regulate various intracellular signaling pathways, like flavonoids, beta-carotenes, lycopene, omega-3 and omega-6 fatty acids, thiol antioxidants, melatonin, carotenoids, resveratrol, vitamin C and E may be used in targeted adjuvant treatment of asthma. However, given the vast degree of naturally occurring compounds exhibiting potent antioxidant activity and signatory intercepts in intracellular pathways, the current review will limit its approach to flavonoids, in particular to Kaempferol, Quercetin, and Isohamnetin flavonol. Another important aspect behind the selection of flavonoids for the purpose of this review is their stronger antioxidant property compared to many other natural antioxidants including vitamin C and E (Prior & Cao, 2000). The antioxidant activity of flavonoids is dependent on their chemical structure, mainly to the catechol moiety (Van Acker et al., 1996). Additionally, it has been reported that the number of hydroxyl (OH) substitutions correlates with higher antioxidant activity of flavonoids (Amić & Lučić, 2010; Cao, Sofic, & Prior, 1997). Natural molecules like flavonoids possess strong antioxidant activity and their ability to regulate intracellular signaling pathways could be effectively utilized for safer and effective therapeutic approaches.

Kaempferol, a flavonoid found in apples and many berries, has been shown to alleviate airway inflammation and acts as a therapeutic agent for asthmatics (Gong et al., 2013). Niering et al. showed that Kaempferol protects rat liver hepatoma cells against cellular damage induced by H<sub>2</sub>O<sub>2</sub> (Niering et al., 2005). Similarly, Kaempferol has also been found to block cerebellar granule cell death, and as a potent inhibition of ROS and superoxide anion production by cerebellar granule cells (Samhan-Arias, Martin-Romero, & Gutierrez-Merino, 2004). Animal studies indicate a favorable response of Kaempferol in reduction of airway inflammation. In airway epithelial cells, Kaempferol was found to inhibit LPS-induced IL-8 production and eotaxin-1 via TLR4 activation. The same study, performed on an ovalbumin sensitized mice model treated with Kaempferol, reported reduction in the levels of CXCR2 and CCR3 along with inhibition of Tyk2-STAT1/3 signaling (Gong et al., 2013). Similar results were obtained in a study where Astragaloside, a 3-O-glucoside of Kaempferol, was found to inhibit LPS and H<sub>2</sub>O<sub>2</sub> induced oxidative stress in airway epithelial cells through inhibition of eotaxin-1 and epithelial apoptosis, and TLR4-PKC $\beta$ -NADPH signaling (Cho et al., 2014). The effect of Kaempferol in NF- $\kappa$ B signaling was further confirmed in a model of TNF- $\alpha$  induced lung inflammation, where a potent inhibitory effect of Kaempferol on monocyte chemoattractant protein-1 transcription involving modulation of NF- $\kappa$ B signaling was reported (Gong, Shin, Han, Kim, & Kang, 2012).

Another vastly studied dietary flavonoid is Quercetin, commonly found in vegetables, fruits, seeds, nuts, tea, and wine, and is known to have strong effects on ROS metabolism and cell apoptosis (Formica & Regelson, 1995; Jeong, An, Kwon, Rhee, & Lee, 2009). In a study of sarcoidosis, an inflammatory disease that mostly affects lungs and lymph nodes, Quercetin supplementation showed a marked reduction in the levels of Malondialdehyde, TNF $\alpha$ /IL-10, and IL-8/IL-10, which are markers of oxidative damage (Boots, Drent, de Boer, Bast, & Haenen, 2011). The authors correlated the observed benefits with a potential role of Quercetin as a ROS and oxidant scavenger, along with its known ability to reduce inflammatory cytokine production (in particular TNF $\alpha$ ) via modulation of NF- $\kappa$ B1 and I $\kappa$ B pathways

(Nair et al., 2006). Moreover, supplementation of Quercetin in a rat model of hepatopulmonary syndrome showed anti-angiogenic effects associated with AKT/NF- $\kappa$ B and VEGFA/VEGFR-2 pathways (Li et al., 2016). Another study with Quercetin treatment on a bleomycin-induced pulmonary fibrosis model showed that oral Quercetin revived anti-oxidant defense mechanisms of the lung along with restoration of lung pathology (Verma et al., 2013). Similarly, Quercetin was able to alleviate radiation-induced oxidative stress, pneumonitis, and fibrosis (H. Liu, Xue, Li, Ao, & Lu, 2013), as well as LPS-induced lung injury (Huang, Zhong, & Wu, 2015). The beneficial effect of Quercetin involving TLR modulation was further established in a study on mouse alveolar macrophage cultures, where Quercetin attenuated TLR7-induced expression of TNF- $\alpha$  and IL-6 (Yasui et al., 2015). Finally, in another study on LPS-stimulated human peripheral blood mononuclear cells (PBMCs), Quercetin was able to suppress the secretion of TNF- $\alpha$ , IL-1 $\beta$ , and IL-6 from PBMCs, and reduced the mRNA expression of TLR2 and NF- $\kappa$ B (Zhang, Lin, Li, & Li, 2016).

Isohamnetin, a flavonol and methylated metabolite of Quercetin commonly found in numerous plant-based foods like almonds, fennel, red onion, and turnip greens, has been reported to have potent anti-inflammatory, anti-oxidative, and anti-proliferative effects. Studies using Isohamnetin have shown that it antagonizes H<sub>2</sub>O<sub>2</sub>, reduces apoptotic damage via inhibition of cytochrome C release, and alters caspase 3 possibly via ERK inactivation in cardiomyocytes (Sun et al., 2012). In addition, Isohamnetin is a potent in vitro and in vivo inhibitor of influenza virus titer, an observation associated with reduction in ROS generation and blockage of cytoplasmic lysosome acidification (Abdal Dayem, Choi, Kim, & Cho, 2015). It also possesses photo-protective properties, and can inhibit cell damage and apoptosis caused by ultraviolet-B exposure by reducing ROS and attenuating oxidative modification of DNA, lipids, and proteins (Han et al., 2015).

In a model of LPS-induced acute lung injury, Chi et al. showed that Isohamnetin treatment is protective against oxidative damage and inflammation via inhibition of TNF- $\alpha$ , IL-1 $\beta$  and IL-6 secretion and suppression of ERK, JNK, I $\kappa$ B $\alpha$ , and NF- $\kappa$ B(p65) phosphorylation (Chi et al., 2016). In a rat model of type 2 diabetes, Isohamnetin decreased the levels of urinary osteopontin, kidney injury molecule 1 (KIM-1), and albumin, and also inhibited production of inflammatory mediators and attenuated oxidative stress possibly via modulation of NF- $\kappa$ B signaling activity (Qiu, Sun, Zhang, Li, & Wang, 2016). In human breast carcinoma cells, Isohamnetin significantly inhibited adhesion, migration, and invasion of carcinoma cells by possibly downregulating the expression of MMP-2 and MMP-9 via suppression of p38 MAPK and ST-AT3. Notably, regulation of MMP-2 and MMP-9 has established links with NF- $\kappa$ B pathway modulation, and the observed reduction in MMPs may have a possible correlation with this pathway (Li et al., 2015; Shishodia, Majumdar, Banerjee, & Aggarwal, 2003). Isohamnetin also modulated TLR activity and offered protection against oxidative stress in an animal model of influenza infection, where it increased TLR2/4 expression in a dose-dependent manner (Wang et al., 2012). Furthermore, in a mouse model of LPS-induced endotoxemia, Isohamnetin reduced peritoneal macrophages NO production, and IL-6, TNF- $\alpha$ , CD40, COX-2 and iNOS expression (Jayashankar, Mishra, Ganju, & Singh, 2014). These observations may indicate a correlation with TLR modulation, as induction of COX-2 and iNOS are associated with TLR4, and play pivotal roles in the development of inflammatory diseases (Shweash et al., 2011). In fact, COX-2 and iNOS have also been identified as potential therapeutic targets in other inflammatory diseases such as cancer (Murakami & Ohigashi, 2007). A study on Mycobacteria-induced lung inflammation showed that Isohamnetin also possesses moderate anti-mycobacterial activities in the lung, and is a potent anti-inflammatory agent, reducing expression of IL-1 $\beta$ , IL-6, IL-12, TNF- $\alpha$ , and MMP-1 and inhibiting MAPK and ERK phosphorylation, a signatory fingerprint in Mycobacterial signaling pathway activation (Jnawali et al., 2016).

Taken together, these studies indicate that flavonol compounds can

be developed as therapeutic candidates for inflammatory lung disease, not only due to their direct protective effects as antioxidants for oxygen and nitrogen scavenging, but also because of their modulatory effects on cell signaling cascades related to lung inflammation and pathology.

## 9. Conclusion and future directions

Asthma therapy can be primarily classified into three classes: inhaled  $\beta$ 2-adrenoceptor ( $\beta$ 2-AR) agonists, inhaled and systemic corticosteroids, and leukotriene synthesis inhibitors (LTSIs) together with leukotriene receptor antagonists (LTRAs) (Sayers & Hall, 2005). Corticosteroids and bronchodilators are the first line and most commonly used drugs to treat typical symptoms of asthma and exacerbations. At a cellular level, corticosteroids increase  $\beta$ -adrenergic responses, diminish the inflammatory cells in the airways, and offer clinical improvement. However, in severe asthma, and in COPD, corticosteroids are ineffective and offer negligible clinical improvement (Barnes, 2013; Belvisi, Hele, & Birrell, 2004; Brusselle, Joos, & Bracke, 2011; Kirkham & Rahman, 2006; I. Rahman, Morrison, Donaldson, & MacNee, 1996). The observed inefficacy of corticosteroids in the treatment of severe lung inflammation is attributed to oxidative stress, chromatin remodeling, and DNA damage that lead to decreased activity of transcriptional corepressors such as histone deacetylase-2 (HDAC-2), known to counteract histones acetylation, resulting in increased expression of inflammatory genes (Zuo, Lucas, Fortuna, Chuang, & Best, 2015). There are at least twelve known mammalian HDACs, which are differentially expressed and regulated in different cell types (Haberland, Montgomery, & Olson, 2009), and are attributed to the observed differences in responsiveness to corticosteroids. Activated pro-inflammatory transcription factors like NF- $\kappa$ B, which is also sensitive to corticosteroids treatment (Barnes, 2004; Barnes, Ito, & Adcock, 2004; Barnes & Karin, 1997), bind to specific sequences in DNA and subsequently interact with coactivator molecules like p300/CREB (cyclic adenosine monophosphate response element-binding protein)-binding protein (CBP) to control target gene transcription.

The  $\beta$ 2-adrenergic receptor agonists act by binding to the  $\beta$ 2-adrenergic receptor, a G-protein-coupled receptor protein encoded by ADRB2 gene, which is expressed on multiple airway cell types (Ortega, Hawkins, Peters, & Bleeker, 2007). ADRB2 is a highly polymorphic gene that can influence lung function, and also respond to  $\beta$ -agonist therapy (Fuso et al., 2013; Green, Turki, Bejarano, Hall, & Liggett, 1995; Hawkins et al., 2006; Martinez, Graves, Baldini, Solomon, & Erickson, 1997; Tan, Hall, Dewar, Dow, & Lipworth, 1997). Similarly, drugs targeting leukotriene signaling pathways are shown to decrease asthmatic exacerbations when coupled with corticosteroid therapy (Camargo et al., 2010; Camargo, Smithline, Malice, Green, & Reiss, 2003; Dahlen, 2006; Philip et al., 2010). However, further research on leukotrienes show that genetic polymorphisms in genes encoding target proteins of the leukotriene pathway may alter the response to LTSIs and LTRAs (Drazen et al., 1999; In et al., 1997; Lima et al., 2006; Sampson et al., 2000). In view of advantages and disadvantages of current therapeutic regimes for asthma, and with the fast increase in the number of asthmatics as reported by the global asthma report (2014) (Network, 2014), there is a dire need for new and alternative therapeutic approaches. Considering that ROS and formation of other oxidants are common in asthma; novel therapeutics targeting redox abnormalities and signaling molecules could be effectively utilized for the treatment of asthma.

At certain concentrations, ROS and other oxidants not only possess direct cell damaging properties, but can also influence cell signaling pathways and molecules at cytoplasmic and nuclear levels. In this context, ROS modulation of PRRs like TLRs in the vicinity of airway antigens, and further modulation of intrinsic signaling molecules like NF- $\kappa$ B are of absolute importance in devising future strategies for better therapeutic control of the clinical features of asthma. The polyphenolic plant secondary metabolites, flavonols, are known to have powerful

antioxidant, anti-allergic, anti-inflammatory and immune-modulating effects. We believe further evaluation of molecular mechanisms involved in the anti-inflammatory properties offered by various flavonols can pave the way for the development of novel therapeutic targets for asthma and other diseases characterized by airway inflammation.

## Conflict of interest statement

The authors have no conflict of interest to declare.
